UV IDENTIFICATION SUBSTITUTION POSITION OF PYRIMIDINE RING**ZASTOSOWANIE SPEKTROSKOPII UV W IDENTYFIKACJI POŁOŻENIA PODSTAWNIKÓW
W PIERŚCIENIU PIRYMIDYNOWYM**

Department of Biochemistry Nicolaus Copernicus University in Toruń, Collegium Medicum in Bydgoszcz

S u m m a r y

Pyrimidine is six-member heterocyclic compound that contains two nitrogen atoms at positions 1 and 3. Pyrimidine derivatives have showed various biological activities such as antimicrobial, antitumor, antifungal, the hypnotic and sedative activities. The oxopyrimidines of the biological activity of the most possess substituents at the *N*1 or *N*3 position [1-11].

This paper presents identification the location of the *N*1 and *N*3 isomeric substituents of the pyrimidine derivatives. The UV spectroscopy was used for this purpose. This method is simple, economical and does not require large quantities of sample.

The absorption maxima of the 1 and 3-substituted pyrimidine derivatives were sensitive to the addition of base.

In alkaline solution the *N*3-alkyl substituted uracil showed bathochromic shift, but the absorption maxima of *N*1 analogs shift toward shorter wavelengths (the hypsochromic shift) (Figure 1, 2, 3). This was associated with the formation of monoanion, which was created as a result of dissociation of a proton from the nitrogen atom (Scheme 2).

The results were compared with the results that may be obtained from the analysis of proton nuclear magnetic resonance ¹H NMR (Scheme 1, 3, 4). The NMR spectroscopy is a method much more precise and it can provide more information about the structure of the compound. By ¹H NMR is not always possible clearly distinguish between *N*1 and *N*3 isomers, in contrast to the UV spectroscopy.

S t r e s z c z e n i e

Pirimdyna jest jednopierścieniowym, sześcioczłonowym heterocyklicznym związkiem aromatycznym zawierającym dwa atomy azotu w pozycji 1 i 3. Jej pochodne zawierające podstawniki w pozycji *N*1 i *N*3 wykazują aktywność biologiczną i znajdują zastosowanie jako środki przeciwbakteryjne, przeciwgrzybicze, przeciwnowotworowe oraz uspokajające i nasenne [1-11].

W pracy została przedstawiona identyfikacja położenia podstawników w izomerycznych *N*1 i *N*3 pochodnych pirymidynowych. Do tego celu wykorzystano prostą, ekonomiczną, niewymagającą dużych ilości próbki metodę – spektroskopię UV. Wykonane w środowisku zasadowym widma UV pochodnych *N*1 podstawnionych pochodnych uracylu wykazują charakterystyczne przesunięcie hipsochromowe maksimum absorbancji w stosunku do widma wykonalnego w pH = 7 (rys. 1, 2, 3). Efekt ten jest spowodowany powstawaniem monoanionu przez dysocjację protonu z azotu

*N*3 (schemat 2). Natomiast dysocjacja protonu z azotu *N*1 w *N*3 podstawnionych pochodnych uracylu prowadzi do powstania monoanionu z układem o znacznie silniejszym sprzężeniu (schemat 2). Wykonane w środowisku zasadowym widma UV tych związków wykazują charakterystyczne przesunięcie maksimum absorbancji w kierunku dłuższych fal – efekt batochromowy (rys. 1, 2, 3).

Uzyskane wyniki zostały porównane z wynikami analizy widma protonowego rezonansu jądrowego (¹H NMR) (schemat 1, 3, 4). Spektroskopia NMR jest metodą znacznie bardziej dokładną. Można dzięki niej uzyskać więcej informacji o strukturze chemicznej badanego związku. Niestety, specyfika metody nie zawsze pozwala na rozróżnienie izomerycznych pochodnych *N*1 i *N*3 pirymidyny. Natomiast analiza widma UV pozwala w każdym przypadku w sposób jednoznaczny określić położenie podstawnika w pierścieniu pirymidynowym.

Slowa kluczowe: spektroskopia UV i ^1H NMR, $N1$ i $N3$ -alkilowe pochodne uracylu, efekt batochromowy, efekt hipsochromowy

INTRODUCTION

The pyrimidine nucleus has a key feature in various derivatives that are used as drugs. A number of pyrimidine bases have been shown to possess antiviral and anticancer activities [1-6], particularly uracils possessing halogens at the 5-position e.g. 5-fluorouracil, 5-iodouracil and their $N1$ and $N3$ analogs [7-9]. The oxypyrimidines such as $N1$, $N3$ -disubstituted uracils were reported to exhibit antibacterial and antifungal activities [10] the hypnotic and sedative activities [11].

This paper presents how one can distinguish between $N1$ and $N3$ uracils derivatives using UV spectroscopy. This method is compared with nuclear magnetic resonance (NMR).

EXPERIMENTAL SECTION

MATERIAL AND METHODS

The chemicals for synthesis of all compounds were from the POCH Chemical Company and used without further purification. The solvents were spectroscopic grade. ^1H NMR spectra were recorded on Bruker apparatus (TMS as an internal standard) in CDCl_3 . Chemical shift are expressed in δ unit (ppm). Ultraviolet-visible (UV-Vis) absorption spectra were recorded on Aquarius 7250 spectrophotometer (Cecil).

6	268.5	2.675	268	2.835	289	3.277

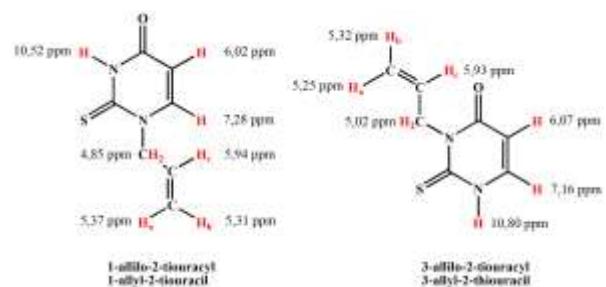

A change of λ_{\max} was investigated when 1 mL base (NaOH , 3×10^3 mol/dm 3) or 1 mL acid (HCl , 3×10^3

mol/dm 3) was added to 250 μl the solution of samples (0.001 mol/dm 3 in ethanol) and 1750 μl distilled water.

Compounds **1-6** were obtained according to literature procedure [12-14]. The molar extinction coefficients and λ_{\max} are shown in the table I.

RESULTS AND DISCUSSION

The results obtained from the ^1H NMR and UV spectrum to determine the position of the substituents on the uracil derivatives were compared. The structure and the chemical shifts for 1-allyl- and 3-allyl-2-thiouracil are shown below (Scheme 1).

Scheme 1. The proton chemical shifts of 1-allyl-2-thiouracil and 3-allyl-2-thiouracil

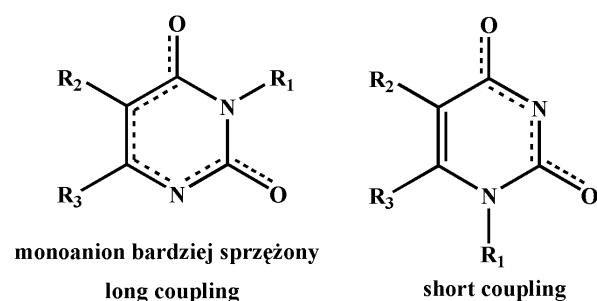

Schemat. 1. Przesunięcia chemiczne protonów 1-allylo-2-thiouracylu i 3-allylo-2-thiouracylu

On the basis of chemical shift in ^1H NMR spectrum cannot be concluded at which the nitrogen atom is located the allyl substituent. More information enabling the identification the $N1$ (**1**) and $N3$ of the 2-thiouracil (**2**) can be deduced on the basis of spin-spin coupling. The protons C-5 and C-6 of the pyrimidine ring are of particular interest.

In the case of 3-allyl-2-thiouracil, the signal for the C-5-H appears in the spectrum as a four peaks. The signal for C-5-H is split into a doublet due to C-6-H with the coupling constant $J_{\text{C}5-\text{C}6}$ (7.6 Hz), and this doublet is split into a doublet of doublets by $N1$ -H with the small coupling constant $J_{\text{C}5-\text{N}1}$ (1.2 Hz). Similarly, the proton signal of C-6 is split into a doublet of doublets with the coupling constant $J_{\text{C}5-\text{C}6}$ 7.6 Hz, and the much larger coupling constant $J_{\text{C}5-\text{N}1}$ 5.8 Hz. Both coupling constants have a relatively large value (short-range coupling), because the C-5-H and the $N1$ -H are in close vicinity of C-6-H. Hence the nitrogen atom at position $N1$ is not substituted. The analysis of the ^1H NMR spectra can unequivocally state that it is 3-allyl-2-thiouracil.

The signal C-5-H of 1-allyl-2-tiouracil splits a doubled doublet. Next to the short-range coupling constant J_{C5-C6} (8.0 Hz) of the C-6-H, can be read from the spectrum of the additional coupling constant (2.1 Hz) of the N3-H (long-range coupling). By contrast, the signal of C-6-H is split only into a doublet with the same coupling constant J_{C5-C6} 8.0 Hz. There is no coupling constant J_{C5-N3} , which shows the lack of a proton at N1. This clearly indicates that the N1 is substituted with the allyl group.

The position of the allyl in 2-thiouracil can be confirmed by performing the UV absorption spectrum. The absorption maxima of the 1 and 3-substituted pyrimidine derivatives were sensitive to the addition of base. The absorption spectra in an alkaline medium for the various 1-substituted uracil show that there is a general tendency for the absorption band to move (1-3 nm) hypsochromically (band shift towards shorter wavelengths). However, in the 3-substituted analogs of pyrimidine bases bathochromic shift (30 nm) can be observed which is characteristic for the compounds of the absorption band shift toward longer wavelengths. This change in the spectrum is explained by the transformation of the substance into monoanion-form. In an alkaline environment free protons at the nitrogen atoms dissociate in both the 1 and 3-substituted uracil. The dissociation constant for these weak acid is practically the same and is about $pK = 11$. The structure of monoanions shown in the scheme 2.

Scheme. 2. The monoanions N1 and N3 of the pyrimidine derivatives

Schemat. 2. Monoaniony N1 i N3 pochodnych pirymidynowych

On the basis of UV spectra can be assigned the position of the allyl group at 1 and 3-substituted pyrimidine derivatives. In an alkaline medium ($pH = 12$) had a characteristic slightly hypsochromic shift for the N1 derivative and a significant bathochromic shift 3-substituted 2-thiouracil. The absorption band of 1-allyl-2-thiouracil was at 268 nm ($\Delta\lambda_{max} = 2$ nm). In contrast, for the N3 analog showing the absorption band shift toward longer wavelengths with an

absorption maximum at 315 nm ($\Delta\lambda_{max} = 30$ nm). The value of the molar extinction coefficient for the derivative at the $pH = 12$ is lower than at the $pH = 4$ and $pH = 7$. The absorption spectra of compounds **1** and **2** in various pH are shown in figure 1.

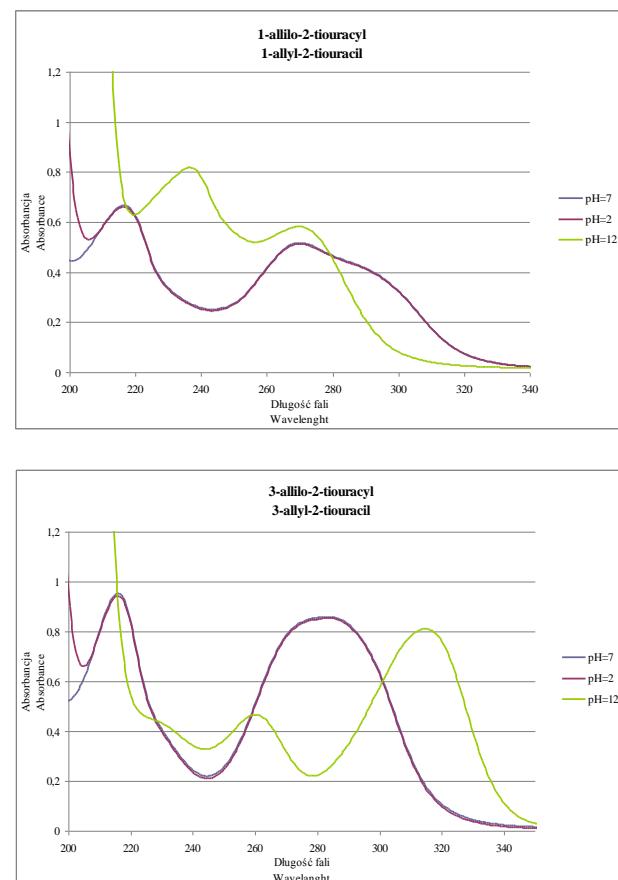

Fig. 1. The UV spectrum of 1-allyl-2-thiouracil and 3-allyl-2-thiouracil

Rys. 1. Widmo UV 1-allilo-2-tiouracylu i 3-allilo-2-tiouracylu

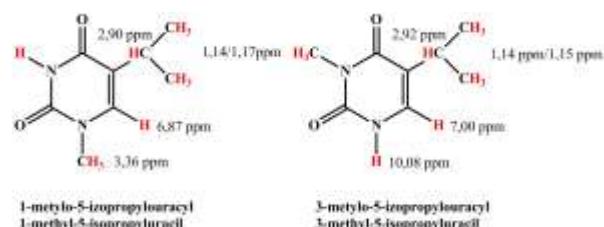

The UV spectrum of 2-thiouracil derivatives completely confirmed the results obtained, which allows determination of the position of the rest of the allyl in pyrimidine ring.

The 1H NMR spectra also in the case of 1-methyl-**(3)** and 3-methyl-5-isopropyluracil **(4)** allows the identification of the position of the methyl substituent in the pyrimidine ring. However, information obtained from the 1H NMR spectrum are poorer. This is due to the absence of a proton at position 5.

The scheme 3 shows the structure and the chemical shifts of the protons of 1-methyl- and 3-methyl-5-isopropyluracil.

In order to confirm the location of the substituent calculated coupling constants C-6 proton. The 1H NMR spectra of **3** showing the doublet with the small coupling constant $J_{C6-Ciso}$ (0.9 Hz). The proton C-6-H in 1-methyl-5-isopropyluracil is coupled to one proton

from isopropyl group with the small coupling constant J_{C_6-Ciso} (0.9 Hz). However, C-6-H in the N3 derivative is coupled to two protons. The C-6-H is split for doublet of doublets with the long-range coupling constant J_{N1-C6} 5.7 Hz and the short-range coupling constant $J_{C6-Ciso}$ 0.9 Hz. This additional coupling constant indicates the close location of the C-6-H and N1-H.

Scheme 3. The proton chemical shifts of 1-methyl-2-isopropyluracil and 3-methyl-2-isopropyluracil

Schemat 3. Przesunięcia chemiczne protonów 1-metylo-5-isopropylouracylu i 3-metylo-5-isopropyluracylu

As in case of 1- and 3-allyl derivatives of 2-thiouracil interpretation of spectra ^1H NMR is used to confirm the structure of these molecules. The UV spectrum confirmed these results (Figure 2).

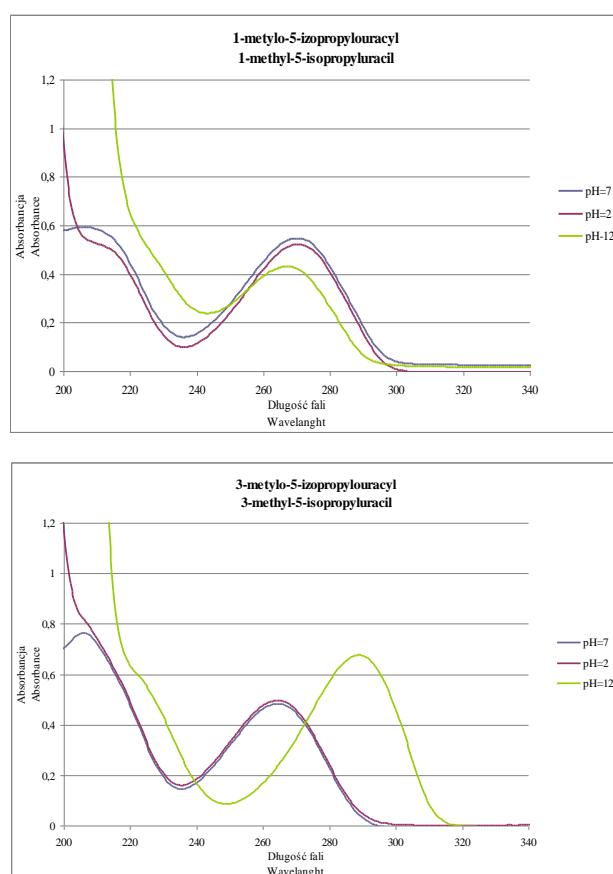

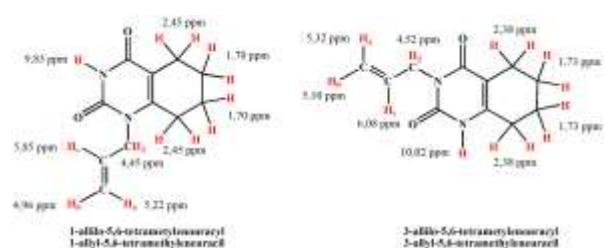

Fig. 2. The UV spectrum of 1-methyl-5-isopropyluracil and 3-methyl-5-isopropyluracil

Rys. 2. Widmo UV 1-metylo-5-isopropylouracylu i 3-metylo-5-isopropylouracylu

The absorption spectrum of 1-methyl-5-isopropyluracil at pH 12 was shifted to shorter wavelengths (269 nm). However, 3-methyl-5-isopropyluracil produced the significant bathochromic shift of the absorption maxima ($\Delta\lambda_{max} = 25$ nm). In this simple way it can be stated clearly at which the nitrogen atom is a methyl substituent.

The situation is quite different in case of a series of 1- (5) and 3-allyl derivatives of 5,6-tetramethyleneuracil (6). The chemical shift values are given below (Scheme 4).

Scheme 4. The proton chemical shifts of 1-allyl-5,6-tetramethyleneuracil and 3-allyl-5,6-tetramethyleneuracil

Schemat 4. Przesunięcia chemiczne protonów 1-allilo-5,6-tetrametylenouracylu i 3-allilo-5,6-tetrametylenouracylu

In these compounds (5 and 6) there are no protons at C-5 and C-6. On the basis of the ^1H NMR spectrum cannot be concluded that the nitrogen atom is substituted. The ^1H NMR spectrum in this case, it becomes unhelpful. In this situation, the implementation of spectrophotometric analysis appears necessary (Figure 3).

As in previous cases, depending on the position of the allyl group in the pyrimidine ring is in the alkaline environment of the characteristic hypsochromic shift for 1-allyl-5,6-tetramethyleneuracil and the bathochromic shift for 3-allyl-5,6-tetramethyleneuracil.

In an alkaline conditions the absorption band was shifted to shorter wavelengths by about 2 nm. At the same time reduction in the molar absorption coefficient was observed in this environment. In contrast, N3 derivative is visible in the spectrum of UV bathochromic shift (about 20 nm) bands of long-term, high molar extinction coefficient. Only UV spectrum clearly confirm position of N-substituent.

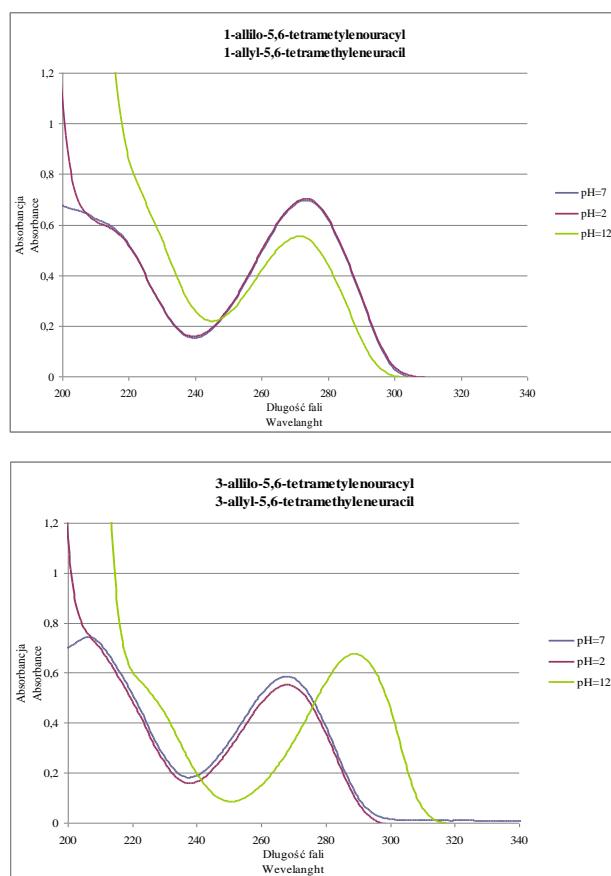

Fig. 3. The UV spectrum of 1-allyl-5,6-tetramethyleneuracil and 3-allyl-5,6-tetramethyleneuracil

Rys. 3. Widmo UV 1-allyl-5,6-tetramethyleneuracylu i 3-allyl-5,6-tetramethyleneuracylu

CONCLUSION

In the present work, we can conclude:

1. The ^1H NMR provides much more information about the structure of the compound; however, when pyrimidine ring does not have the protons C-5 and C-6, identification of isomers of N1 and N3 by NMR is not possible. Without performing spectrophotometric analysis knowledge about the structure of the compound would be incomplete. The UV spectra allows the identification of the substituent in the pyrimidine ring.
2. The absorption spectra in an alkaline medium for the various 1-substituted uracil showed that there is a general tendency for the absorption band to move hypsochromically.
3. The absorption spectra in an alkaline medium for the various 3-substituted uracil produced bathochromic shift.
